

Git Cheat Sheet

Git Basics		Rewriting Git History	
<code>git init</code> «directory»	Create empty Git repo in specified directory. Run with no arguments to initialize the current directory as a git repository.	<code>git commit</code> —amend	Replace the last commit with the staged changes and last commit combined. Use with nothing staged to edit the last commit's message.
<code>git clone</code> «repo»	Clone repo located at «repo» onto local machine. Original repo can be located on the local filesystem or on a remote machine via «url» or «ssh».	<code>git rebase</code> «base»	Rebase the current branch onto «base». «base» can be a commit ID, a branch name, a tag, or a relative reference to HEAD.
<code>git config</code> user.name «name»	Define author name to be used for all commits in current repo. Devs commonly use —global flag to set config options for current user.	<code>git reflog</code>	Show a log of changes to the local repository's HEAD. Add —relative-date flag to show date info or —all to show all refs.
<code>git add</code> «directory»	Stage all changes in «directory» for the next commit. Replace «directory» with a «file» to change a specific file.	Git Branches	
<code>git commit -m</code> «message»	Commit the staged snapshot, but instead of launching a text editor, use «message» as the commit message.	<code>git branch</code>	List all of the branches in your repo. Add a «branch» argument to create a new branch with the name «branch».
<code>git status</code>	List which files are staged, unstaged, and untracked.	<code>git checkout -b</code> «branch»	Create and check out a new branch named «branch». Drop the -b flag to checkout an existing branch.
<code>git log</code>	Display the entire commit history using the default format. For customization see additional options.	<code>git merge</code> «branch»	Merge «branch» into the current branch.
<code>git diff</code>	Show unstaged changes between your index and working directory.	Remote Repositories	
Undoing Changes		<code>git remote add</code> «name» «url»	Create a new connection to a remote repo. After adding a remote, you can use «name» as a shortcut for «url» in other commands.
<code>git revert</code> «commit»	Create new commit that undoes all of the changes made in «commit», then apply it to the current branch.	<code>git fetch</code> «remote» «branch»	Fetches a specific «branch», from the repo. Leave off «branch» to fetch all remote refs.
<code>git reset</code> «file»	Remove «file» from the staging area, but leave the working directory unchanged. This unstages a file without overwriting any changes.	<code>git pull</code> «remote»	Fetch the specified remote's copy of current branch and immediately merge it into the local copy.
<code>git clean -n</code>	Shows which files would be removed from working directory. Use the -f flag in place of the -n flag to execute the clean.	<code>git push</code> «remote» «branch»	Push the branch to «remote», along with necessary commits and objects. Creates named branch in the remote repo if it doesn't exist.
